Predictive Services Discussion: High pressure over the Intermountain West will expand in size and begin to migrate east toward the central Great Plains. Scattered wet and dry storms are expected across both regions as the system begins its eastward trek. The west coast will see near normal temperatures along with breezy winds in the Pacific Northwest. A southerly monsoonal flow beneath the ridge of high pressure will continue to produce scattered showers and storms along with elevated humidities across the Four Corner's region.
Scattered showers and storms are expected across the Southeast as a stalled front slowly drifts south through the Tennessee River Valley. In Alaska, unusually warm and dry conditions will continue with isolated storms developing across western portions of the interior in the afternoon as another disturbance moves on shore from the Bering Strait.

New Research on Safety Zones
Operational Engagement

> [If you have computer or smart phone access, please watch the video for this subject using the link or QR code...Otherwise, read on Old School...]

First, a Fire Behavior 101 refresher: You can warm yourself around the sides of a campfire for quite some time; that's radiant heat. If you hold your hands over the top of the fire, you'll get burned relatively quickly; that's convective heat.

Basically, wind or slope can tip the flames over, so that the convective heat is no longer going straight up, but is now aimed more along the ground, sending the heat and hot gasses much further ahead. This causes pre heating of the fuels, faster fire spread and greater fire intensities. You'll need a larger Safety Zone if that fire is coming towards you.

The current equation for safety zone size in the IRPG (page 8) is:

$$
4 \text { x Flame Height = Safe Separation Distance }
$$

To make estimations of flame height though, you either have to use past fire behavior observations or use your experience to guess what the fire may do in the future. After a decade of research, Bret Butler, at the Missoula Technology and Development Center, suggests removing the uncertainty and guesswork that comes with estimating flame height by taking the general rule of thumb: Flame Height $=2 \times$ Vegetation Height
...and substituting that Flame Height equation into the original IRPG equation, to give:
$4 \times 2 \times$ Vegetation Height $=$ Safe Separation Distance, which simplified is:
$8 \times$ Vegetation Height $=$ Safe Separation Distance

But remember, that's still for radiant heat only, on flat ground, with no wind. To take into account the convective heat from slope or wind, Butler's research suggests that a "Slope Wind Factor" is needed in the equation:

$$
8 \times \text { Vegetation Height x Slope Wind Factor = Safe Separation Distance }
$$

But what is the Slope Wind Factor? Current research is indicating that the Slope Wind Factor is between 1 and 10; with Butler arguing it may be closer to between 1 and 5 . Butler's ongoing research is focused on answering that question by gathering sensor data on fires, running computer simulations, and refining the models...Stay tuned.

In the meantime, utilize the calculations on page 8 of your IRGP to help you determine a bare minimum size for your safety zone with the understanding that slope and wind need to be considered in your decision making.

But remember, a safety zone is only good if you can get there...join us tomorrow for some thoughts on Escape Routes.

[^0]:    * Bravo17, Carson City District, BLM. IMT 2 (Rohrer). IMT is also managing the Draw fire. Twenty-five miles east of Fallon, NV. Closed timber litter, brush and short grass. Active fire behavior with running and spotting.
