Predictive Services Discussion: High pressure remains over the central Plains, with above normal temperatures for the northern Great Basin, Northern Rockies, Plains, and much of the Pacific Northwest. Low relative humidity will continue for the northern Plains into Minnesota, but north winds will be lighter. Dry conditions are expected across the inland Pacific Northwest into northern Idaho and northwest Montana as well. Moisture will remain elevated across much of the West with isolated to scattered mixed wet and dry thunderstorms from northern California into central Oregon and eastward across central Idaho into far southwest Montana. Thunderstorms are likely to turn wetter in southern Montana and Wyoming with severe storms possible in central and eastern Wyoming. Scattered wet thunderstorms are expected in the central and southern Sierra, Great Basin, Colorado Rockies, and Southwest into southeast California. Severe thunderstorms are likely from the Ohio Valley into the Northeast and Mid-Atlantic.

# Safety Zone Research 

Operational Engagement

## [If you have computer or smart phone access, please watch the video for this subject using the

link or QR code...Otherwise, read on Old School...]
First, a Fire Behavior 101 refresher: You can warm yourself around the sides of a campfire for quite some time; that's radiant heat. If you hold your hands over the top of the fire, you'll get burned relatively quickly; that's convective heat.
Basically, wind or slope can tip the flames over, so that the convective heat is no longer going straight up, but is now aimed more along the ground, sending the heat and hot gasses much further ahead. This causes preheating of the fuels, faster fire spread, and greater fire intensities. You'll need a larger safety zone if that fire is coming towards you.
The current equation for safety zone size on the Safety Zones page of the Incident Response Pocket Guide (IRPG), PMS 461:

4 x Flame Height = Safe Separation Distance
To make estimations of flame height though, you either have to use past fire behavior observations or use your experience to guess what the fire may do in the future. After a decade of research, Bret Butler, at the Missoula Technology and Development Center, suggests removing the uncertainty and guesswork that comes with estimating flame height by taking the general rule of thumb:

Flame Height $=2 \times$ Vegetation Height
...and substituting that Flame Height equation into the original IRPG equation, to give:
$4 \times 2 \times$ Vegetation Height $=$ Safe Separation Distance, which simplified is:
$8 \times$ Vegetation Height $=$ Safe Separation Distance
But remember, that's still for radiant heat only, on flat ground, with no wind. To take into account the convective heat from slope or wind, Butler's research suggests that a Slope Wind Factor is needed in the equation:
$8 \times$ Vegetation Height $\times$ Slope Wind Factor $=$ Safe Separation Distance
But what is the Slope Wind Factor? Current research is indicating that the Slope Wind Factor is between 1 and 10, with Butler arguing it may be closer to between 1 and 5 . Butler's ongoing research is focused on answering that question by gathering sensor data on fires, running computer simulations, and refining the models.
In the meantime, utilize the calculations in the Safety Zones page of your IRPG to help you determine a bare minimum size for your safety zone with the understanding that slope and wind need to be considered in your decision-making.
But remember, a safety zone is only good if you can get there.
